(54) **Dispersion process for ceramic green body.**

(57) A process for the preparation of a ceramic green body comprises hydrolyzing two groups of alkoxides to form a dispersion of their reaction product, concentrating the dispersion to a sediment without drying it, and admixing a binder solution, plasticizer and release agent with the sediment to make a ceramic slip. The slip is then cast as a ceramic green body. The proportions of alkoxides can be adjusted, when desired, to produce a ceramic green body which is dielectric and useful for microcapacitors or as a conductor.

EP 0 302 972 A1

DISPERSION PROCESS FOR CERAMIC GREEN BODY

The present invention concerns a process for making a ceramic green body of a type which may be fired into a thin ceramic sheet or tape for use in a multilayer capacitor or as a conductor.

A multilayer capacitor is a stack of a number of ceramic capacitor sheets connected in parallel to produce a capacitor of high total capacitance. These capacitors may be very small, and typically comprise between 40 and 50 ceramic sheets, each about 20 μm thick. The entire capacitor may be only about 1 mm thick. These devices find many uses in microcircuitry.

However, there is a need for even thinner ceramic bodies, within the range of 3 to 10 μm in thickness. This is due to the fact that equivalent capacitance could be achieved using only half as many of these thinner sheets, since capacitance is inversely proportional to the thickness of the ceramic sheet. The reduction in the number of sheets would then result in a savings in material costs, because the electrode layers interspersed between the ceramic layers are made of expensive noble metals, and with fewer, thinner sheets, fewer electrode layers would be required. In the past it has been very difficult to make sheets of this reduced thickness because current commercial methods of producing the green (unfired) tapes involve processing of solids, including ceramic powders.

These ceramic powders, which are dielectric and/or conductive, are dispersed into an organic solvent such as a methyl ethyl ketone/ethanol mixture. The powders are often barium titanate admixed with other compounds such as strontium titanate, lead titanate, calcium zirconate, lead oxide, borates and silicates. Ball-milling is generally necessary to maximize dispersion in the solvent, and often requires several hours at a minimum. The dispersed powders are then mixed with polymeric organic binders, plasticizers and surfactants to form a slip, which is tape-cast onto a nonporous substrate and dried in an oven to form a flexible "green tape."

To produce a capacitor, this green tape or green body is screen-printed with a noble metal electrode ink. Forty or fifty layers, typically, of the printed tape are then laminated and, after dicing into chips or sheets, fired to burn off the organic binder. The inorganic chips are sintered at high temperatures, typically between 1000 and 1400°C, to densify the sheets and improve their strength and conductivity. The result is a mechanically and electrically acceptable device.

A problem very commonly faced in this process, however, that tends to militate against reducing the thickness of the sheets or tapes beyond

thicknesses currently being produced, is the fact that ceramic powders are usually agglomerated when received and remain so to some extent even after lengthy ball-milling prior to and after dispersion in a solvent. This agglomeration makes it difficult to produce sheets of only 3 to 10 μm in thickness that are of uniform quality, since the size and shape of the initial ceramic particles is a critical factor in producing a good quality final product. It also tends to produce sheets that exhibit less than optimum loading levels, and the reduced density increases the degree of shrinkage of the tape during firing. Ideally, the particles should be uniformly sized and equiaxially shaped, and should also demonstrate high purity.

Therefore, because of the problems associated with the ceramic powders and their general unsuitability to producing the thinner ceramic sheets now sought, it would be desirable to have a ceramic green body prepared from a slip formulation which does not generally require ball-milling or other milling steps at any point and for which powder agglomeration does not present a significant problem, which exhibits good ceramic loading levels, and which therefore does not generally require processing of dry ceramic powders, with the accompanying quality problems and thickness limitations that such processing entails. The present disclosure describes such an invention and involves an in situ finely dispersed slurry that may be used to produce a ceramic green body.

Accordingly, there is provided a process comprising (a) forming a hydrolyzable solution of a first group of alkoxides having at least one compound characterized as $A(\text{OR})_x$, wherein A is at least one of the metals Be, Mg, Ca, Sr, Ba, Ge, Pb, Nd, Y, La, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb, Lu, Sb or Bi, a second group of alkoxides having at least one compound characterized as $B(\text{OR})_x$, wherein B is at least one of the metals Ti, Zr, Sc, Y, La, Nb, Fe, Ta, W, Mn, Sn, Mg, Cu or Zn, and wherein R is a compound characterized as C_yH_z , wherein y is an integer from 1 to 10, z is an integer y, 2y, 2y + 1 or 2y - 1, and x is an integer from 1 to 7, such that these first and second groups of alkoxides are suitable to be hydrolyzed to form a compound characterized as ABO_3 , and an alcohol suitable to dissolve said first and second groups of alkoxides; (b) hydrolyzing said hydrolyzable solution to form a hydrolyzed dispersion of this compound characterized as ABO_3 in the alcohol; (c) concentrating at least a portion of the dispersion to a sediment; (d) admixing a binder solution, a plasticizer, and a release agent with the sediment to make a ceramic slip formulation; and (e) preparing

a ceramic green body from this slip formulation.

The process of the present invention can be advantageously used to prepare a ceramic green body from a solution without the need to use ceramic powders. The term "ceramic green body" refers to a body, often a tape or sheet, of a material that can be converted into a ceramic upon firing.

The admixture and hydrolysis of soluble metal alkoxides of the appropriate composition and stoichiometry can lead to the formation of metal oxides that have desirable properties including both insulation and conductivity.

The starting components to be utilized here typically comprise a first group of alkoxides and a second group of alkoxides which are hydrolyzed together and used in forming a hydrolyzed dispersion in alcohol, with which is then admixed at varying points a binder solution, a plasticizer and a release agent. The alcohol and two groups of alkoxides form what is referred to as the "hydrolyzable solution," before hydrolysis, and afterward is referred to as the "hydrolyzed dispersion." The amounts for each of the components of the present invention have been calculated based on either the hydrolyzable solution or the hydrolyzed dispersion. The alcohol generally comprises from 80 to 99 percent by weight of the hydrolyzable solution, and preferably from 90 to 98 percent by weight. The alcohol is preferably selected to minimize, and more preferably avoid, the formation of insoluble alkoxide components through metathetical reactions during the herein disclosed process. Among the preferred alcohols are isopropanol, butanol, sec-butanol, pentanol and isoamyl alcohol. Isopropanol is generally more preferred here.

For the purposes of this invention, the first group of alkoxides desirably comprises at least one of the metals Be, Mg, Ca, Sr, Ba, Ge, Pb, Nd, Y, La, Pm, Sm, Sb, Eu, Bi, Gd, Tb, Dy, Ho, Er, Tm, Yb, or Lu, preferably Be, Mg, Ca, Sr, Ba, Ge, Pb, Y, Sb, La, or Bi, and more preferably Pb, Y, Ca, La, Ba, Mg or Sr. One or more selections from this group of elements is incorporated as A in the alkoxide formula $A(OR)_x$.

The second group of alkoxides comprises at least one compound characterized as $B(OR)_x$, in which B is at least one of the metals Ti, Zr, Sc, Y, La, Nb, Fe, Ta, W, Mn, Mg, Zn, Cu or Sn, preferably Ti, Zr, Sc, Y, La, Nb, W, Sn, Mg, Ta, Cu or Zn, and more preferably Ti, Zr and Cu. The first and second groups of alkoxides together represent from 1 to 20 percent by weight of the hydrolyzable solution, and preferably from 2 to 10 percent by weight.

The R in both of the alkoxide formulas $[A(OR)_x$ and $B(OR)_x]$ represents a compound of the general formula C_yH_z , wherein y is an integer from 1 to 10

and z is an integer y, 2y, $2y + 1$ or $2y - 1$. The x is an integer from 1 to 7. The two groups of alkoxides are dissolved in the alcohol, and are such that they are suitable to be hydrolyzed to form a compound characterized as ABO_3 . It is important to note that one or both of these two groups of alkoxides may comprise mixtures of compounds employing the designated elements.

The hydrolysis of the two groups of alkoxides together is preferred and is accomplished by the addition of a greater than stoichiometric amount of water while heating at reflux temperature. This means that the amount of water to be added is preferably from 0.5 to 10 percent by weight of the hydrolyzable solution, and more preferably from 0.5 to 3.5 percent. In general, this heating should be of sufficient time and temperature to substantially hydrolyze the solution, and is preferably done for at least 1 hour with continued stirring. Alkoxide solutions refluxing within the range of 70 to 110°C are preferred when the alkoxides chosen include barium and titanium because hydrolysis within this temperature range results in the formation of crystallites of $BaTiO_3$ having small, substantially uniform particle size in the 100 to 2000 Å range. Even more preferred are solutions refluxing within the range of 80 to 90°C. Refluxing may be continued as long as desired, but a time within the range of 1/2 hour to 5 hours is preferred, and 1/2 hour to 1 1/2 hours is more preferred, from a standpoint of yield as well as convenience and commercial practicability.

The water is added preferably in an alcohol solution, preferably within the range of 10 to 50 percent water. The water and alcohol should be miscible at whatever percent mixed, and again the alcohol for this hydrolysis is preferably selected to minimize, and more preferably to avoid, the formation of insoluble alkoxide components through metathetical reactions. The rate of addition is useful in determining the desired small particle size and reducing the possibility of undesirable agglomeration. It is preferable to use a rate within the range of 0.2 to 0.4 cubic centimeter per minute (cc/min), more preferably 0.3 to 0.35 cc/min. This latter rate helps produce particles in the 100 to 300 Å range. It is possible to increase the addition rate once an approximately stoichiometric amount of water has been added. If the water is added too rapidly at the start, however, agglomerates may form.

The hydrolysis step results in the conversion of the coordination compound formed by the first and second groups of alkoxides in the alcohol to a dispersion of the compound characterized as ABO_3 . ABO_3 preferably comprises combinations of $BaTiO_3$ and from 2 to 20 mol percent of such others of the same characterization as $CaZrO_3$, $BaZrO_3$, $PbTiO_3$ and $SrTiO_3$. Other possibilities

here include, for example, CaTiO_3 , MgTiO_3 , SrZrO_3 , BaYCuO_3 , and related compounds in which any of the designated alkoxide elements is present.

It should be noted that the ABO_3 system, which is the hydrolyzed dispersion, ideally displays a small particle size along with a narrow size distribution and substantial uniformity of stoichiometry between the first and second groups of alkoxides. It is preferable to use substantially stoichiometric proportions of these two groups of alkoxides to produce a body exhibiting significant dielectric characteristics. A preferred range is a ratio between the two groups of alkoxides of 1.1 to 1, more preferably 1.05 to 1, and most preferably 1.01 to 1. If dielectric properties are not of importance to a desired application, the proportionality is correspondingly less important. The small and uniform particle size helps to ensure uniform sintering and reduces the likelihood of flaws in the final ceramic green body.

Following the hydrolysis, it is optional to remove the water remaining in a separate step. For this, an azeotropic distillation, for example, may be done so that a substantially dry alcoholic slurry results. Residual water may still be left and will not affect the final outcome as long as the water content is sufficiently low so as not to create binder solubility problems. Other drying methods including, for example, the use of agents such as 1,2-dimethoxypropane, may alternatively be employed. This step is not per se necessary, however, since the subsequent concentration step, described below, serves to minimize the amount of water remaining in the final slip formulation.

A dispersant may be added at this point, in the amount of preferably from 0.002 to 0.5 percent by weight of the hydrolyzed dispersion, and more preferably 0.008 to 0.05 percent by weight. It is alternatively possible to add it to the original alkoxide solution prior to hydrolysis, or to the hydrolyzed dispersion prior to the drying step; however, if drying is done by distillation, a substantial loss of the dispersant may result, which may in turn allow greater agglomeration afterward. Among possible dispersants are, for example, anionic dispersants such as amine salts of alkylaryl sulfonate, ethanol, polyacrylate, methacrylate or menhaden fish oil. Ethanol and amine salts of alkylaryl sulfonate are preferred here, and since ethanol may also be chosen as the alcohol for the original dispersion's formation, a separate dispersant addition may be thereby obviated. The dispersant serves to increase the uniformity and reduce the agglomeration of the ABO_3 dispersion.

While the present invention is not limited to a strict order of steps in all respects, obvious limitations will apply in order to produce a mechanically

and electrically acceptable device. One step generally occurring after the hydrolysis is the concentration of the disperse, or internal, phase to a nonisolated sediment in a greatly reduced volume of the continuous, or external, phase. The remaining volume of the continuous phase, which is primarily alcohol, is ideally just sufficient to maintain the ABO_3 in a nonagglomerated state. Experimentally, this was determined essentially visually. The amount of continuous phase remaining may be determined, for example, by measuring the volume of distillate collected during the drying/concentration step or by the liquid content of the sedimentation volume following gravimetric settling or centrifugation.

Centrifugation provides one effective means of concentration without complete isolation from the continuous phase and is the preferred method. Other means may include distillation, decantation (gravitational sedimentation), or combinations of these procedures. Complete isolation, i.e., drying of the sediment, at any point should be avoided both because of the undesirable agglomeration that will result and because of the difficulty of redispersing the formulation if it has dried. An important point of this invention, as already noted, is that the formulation remains a slurry throughout the processing.

Another important point to the present invention is that it employs a binder solution. The binder serves to help disperse the solids and to stabilize the suspension, and also provides integrity and strength to the final product. If concentration is by distillation, the binder solution may be added prior to concentration, provided that the dispersion, or suspension, is sufficiently water-free. However, in all cases, and especially in the cases of concentration by centrifugation and by gravitational settling, addition of the binder solution after concentration minimizes the loss of binder in the discarded external phase.

The solvent employed for the binder can be aqueous or nonaqueous, with the solvent choice obviously depending on the binder choice. Examples of possible solvents include toluene, methyl ethyl ketone, methanol or a methanol/water mixture, with toluene being preferred. If an organic-based system is chosen, ethylcellulose makes an excellent binder. Other organic binder systems are those using ethyl hydroxyethyl cellulose and polyacrylic acid esters. For a water-based system, polymers such as methylcellulose, hydroxypropyl ethylcellulose, hydroxybutyl methylcellulose, carboxymethylcellulose, hydroxyethylcellulose, polyvinylalcohols, polyvinylpyrrolidones, poly(acrylic acid), polyacrylamide, polyethylene oxides and mixtures of these polymers can be employed as binders in formulating the slip. The cellulose ethers are preferred binders, and more preferred here is

water-soluble methylcellulose. Obviously, an aqueous binder system obviates the need to substantially remove water from the hydrolyzed dispersion.

The use of these and related binders will help to form a very uniform slip that upon casting forms a thin transparent film, indicating good uniformity of metal oxide particulates and binder particulates. The particulates range from 100 to 2000 Å in size. The binder solvent represents preferably from 1 to 6 percent by weight of the hydrolyzed dispersion, and more preferably from 2 to 4 percent by weight. The binder itself is preferably from 0.1 to 5 percent by weight, and more preferably from 0.1 to 1 percent by weight.

A release agent, such as a polyol or mineral oil, may also be added to the binder solution prior to adding the solution to the dispersion. This serves to facilitate easy stripping of the green tape from the casting substrate. When using a glass substrate, 1,2,4-butanetriol makes an excellent release agent. Nonglass substrates, such as polypropylene, may also be used while employing other release agents. The release agent preferably amounts from 0.01 to 5 percent by weight of the hydrolyzed dispersion, and more preferably from 0.05 to 3 percent by weight.

In the present invention, a plasticizer is also employed and serves to lower the glass transition point of the binder to ambient or room temperature to increase the flexibility of the film, thereby making the green body or tape more easily removed from the substrate and more suitable for lamination. Examples of typical plasticizers include dimethyl formamide and propylene glycol, both of which are particularly effective in a methylcellulose aqueous solution, and dioctyl phthalate and benzyl butyl phthalate, both of which work well in an ethylcellulose organic-based system. For an ethylcellulose binder solution, dioctyl phthalate and benzyl butyl phthalate are preferred plasticizers. The plasticizer is added preferably in an amount of from 0.01 to 5 percent by weight of the hydrolyzed dispersion, and more preferably from 0.05 to 3 percent by weight.

It is important when adding the binder solution containing the plasticizer and release agent to the ABO_3 dispersion to use some means to keep the viscosity of the dispersion as low as possible. This should be done both during and after the addition of the binder. Means such as the use of appropriate commercially available surfactants may be employed when necessary to avoid agglomeration.

The final component of the slip formulation is optionally one or more sintering aids. For these, low-melting eutectic oxide mixtures may be employed, including compounds such as GeO_2 , B_2O_3 , PbO , Bi_2O_3 , $\text{TiO}_2\text{Sb}_2\text{O}_3$, SnO , and SiO_2 , preferably GeO_2 , B_2O_3 , PbO , Bi_2O_3 , Sb_2O_3 , and SnO . There

are various ways in which one or more of these can be added so that they can perform their function of densifying the ceramic film and thereby increasing its strength and dielectric properties. In one preferred embodiment a third group of alkoxides of a type that will form sintering aids, such as glass frits, upon hydrolysis is selected. This group is then hydrolyzed in alcohol either concurrently with the first and second groups of alkoxides, in a step-wise fashion before or after the hydrolysis of the first and second groups, or entirely separately from the first and second groups. In the latter case the eutectic oxide mixture may be added at any subsequent point in the process of the present invention, such as prior to or after concentration or along with the addition of binder solution, plasticizer, release agent and so forth. Alternatively, the sintering aid to be employed may be purchased commercially, obviating the need for hydrolyzing a third group of alkoxides. The amount used represents from 0.01 to 2 percent by weight of the hydrolyzed dispersion, and preferably from 0.03 to 0.2 percent by weight. To further augment the dielectric properties of the final film, dopants that will form MnO , Mn_2O_3 , CoO , or Co_2O_3 may also be added, but they are not necessary to the present invention.

The last step of this process involves the conversion of the uniform concentrated dispersion into a ceramic green body using known methods, such as curtain-coating, tape-casting or doctor-blading. It is preferred to tape-cast a single layer of the non-isolated dispersion sediment onto a nonporous substrate. The techniques for converting slip formulations into flexible green tapes are well known. For example, see the chapter "Tape-Casting of Ceramics" in Ceramic Processing Before Firing, edited by G. Y. Onada, Jr. and L. L. Hench, John Wiley and Sons, Inc., N.Y. (1978), pp. 411-447.

The green body prepared according to the process of the present invention can then be converted using known methods into a thin ceramic sheet or tape. Typically, the green body is calcined to burn off the polymer and to convert the tape or sheet to a ceramic material. This is then sintered, or fired, at a temperature of from 1000 to 1400° C. Advantageously, the green body of the present invention exhibits a good loading level which tends to reduce shrinkage upon firing. Preferably, the fired ceramic sheets, which may also be called films, of the present invention range from 1 to 50 μm in thickness, more preferably from 3 to 10 μm. They can be employed in the preparation of capacitors or conductors which have a reduced volume compared to many known capacitors or conductors due to the increased capacitance of the thinner sheets. Thus, these capacitors may be less expensive to produce than many known capacitors

because they require fewer noble metal electrode layers.

It should be noted that steps necessary to the present invention, regardless of order taken, include the preparation of a hydrolyzed dispersion of the first and second groups of alkoxides, provided hydrolysis of these two groups occurs together, the concentration of the dispersion, and the addition of binder solution, plasticizer and release agent to make a slp formulation to be used in preparing a ceramic green body. The order of addition of the binder solution, plasticizer and release agent may be varied. As noted, for example, the binder solution, plasticizer and release agent, or any combination thereof, may be added prior to the concentration, although it is preferable to add these after the concentration to minimize their loss in any discarded external phase. The optional dispersant cannot be added before the hydrolysis, but may be added either before or after an optional drying step. Hydrolysis itself may be done in more than one step, with a third group of alkoxides hydrolyzed in order to supply the optional sintering aids, and then the first and second groups of alkoxides added for a second hydrolysis, for example, or in reverse order. Other variations in order are also possible, including having more than one addition step for a given component, as long as the weight percent ranges are satisfied. As noted, commercial sintering aids may alternatively be used and dispersed at various points in the process.

The following examples are given to illustrate the present invention and are not intended to be, nor should they be construed as being, limitative in any way of the scope of the invention. All parts and percentages are by weight unless otherwise indicated.

Example 1

About 6.2 g (0.0218 mole) of titanium isopropoxide $[\text{Ti}(\text{i-C}_3\text{H}_7\text{O})_4]$, 6.8 g (0.0215 mole) of barium isopropoxide isopropylate $[\text{Ba}(\text{i-C}_3\text{H}_7\text{O})_2\text{C}_3\text{H}_7\text{OH}]$, and 150 ml of isopropanol were added to a 500 ml Schlenk flask in a dry box. The admixture was refluxed over argon for 30 minutes to produce a colorless solution.

A solution of 5 ml water and 5 ml isopropanol was then added to the refluxing solution at the rate of about 0.2 ml/min. The water/isopropanol solution had been degassed previously. The addition was made via a 1/16" (0.16 cm) cannular tube and the solution was continually stirred during the addition. At this point the reaction mix showed a dispersion of finely divided white particles. Refluxing was continued for about 2 hours, and the solution allowed to cool naturally.

The final product, a milky dispersion, was then allowed to sit in a graduated cylinder at room temperature. There was produced a gravitational sediment volume of 25 ml in which was estimated to be about 3.2 g of BaTiO_3 .

The XRD (x-ray diffraction) pattern of the settled BaTiO_3 showed an average crystallite diameter of 110 Å which would correspond to a surface area of 91 m^2/g . TEM (Transmission Electron Microscopy) showed primary particles (spheres) measuring about 185 Å in diameter.

To a mechanically stirred gravitational sediment volume of this BaTiO_3 (3.2 g/25 cc) prepared in the above manner was added dioctyl phthalate, 0.3 g, as a plasticizer, and 1,2,4-butanetriol, 0.3 g, as a release agent. This dispersion was stirred at 300 rpm for 10 minutes and 0.8 g of ETHOCEL[®] 45 brand ethylcellulose was added over a 30 minute period, as a binder. (ETHOCEL is a trademark of The Dow Chemical Company.) Stirring was then continued an additional 1.5 hours. One ml of a 0.6 percent by weight solution of an amine salt of alkylaryl sulfonate in isopropanol was then added as a dispersant.

An 8.0 mil thick film was cast on glass using a doctor-blade. The film was dried at room temperature in air to produce a translucent 0.7 mil film that was easily stripped from the glass surface. X-ray powder diffraction line broadening measurements of this film showed an average crystallite size of 133 Å. STEM (Scanning Transmission Electron Microscopy) photos showed slightly agglomerated particles with an average primary particle diameter of 200 Å. Thermogravimetric analysis of the film gave a ceramic content of the film of about 67 percent by weight.

Example 2

$\text{Ba}(\text{i-C}_3\text{H}_7\text{O})_2$ (4.63 g, 0.0182 mole), $\text{Sr}(\text{i-C}_3\text{H}_7\text{O})_2$ (0.71 g, 0.0034 mole), $\text{Ti}(\text{i-C}_3\text{H}_7\text{O})_4$ (5.92 g, 95 percent in isopropanol, 0.0197 mole), $\text{Zr}(\text{n-C}_3\text{H}_7\text{O})_4$ (0.75 g, 95 percent in isopropanol, 0.0022 mole) and $\text{Pb}(\text{i-C}_3\text{H}_7\text{O})_2$ (0.14 g, 4.3×10^{-3} mole) were dissolved in 250 ml of dried and deoxygenated isopropanol. The solution was added to a stirred reaction vessel under an inert atmosphere and refluxed for about 45 minutes. A 10 percent by volume solution of distilled water in isopropanol, as a solvent, was added at a rate of about 0.3 ml/min, until a volume of 35 ml was added. The addition rate was then increased to 3 ml/min until a total volume of 100 ml had been delivered. Reflux was continued an additional 1.5 hours during which hydrolysis was substantially completed.

The water was removed by azeotropic distillation and the suspension was then concentrated by

centrifuging at 40 G until a bed volume of 25 ml was obtained. The nonisolated product was estimated to weigh about 5 g and analysis showed it to have the nominal composition: BaTiO₃, 71.77 percent; SrTiO₃, 12.23 percent; BaZrO₃, 11.56 percent; TiO₂, 0.58 percent; and PbO, 3.85 percent.

ETHOCEL 45 ethylcellulose, 1 g, was dissolved in 10 ml of toluene and 1 ml of ethanol, and 0.3 g of dioctyl phthalate and 0.7 g of propylene glycol were added. The solution was then added to the centrifugate and the mixture stirred for about 2 hours. The resultant slip had a viscosity of about 400 centipoise. The slip was then cast by doctor-blade at 5 and 10 mil thicknesses, resulting in transparent dried films of 0.7 and 1.5 mil thicknesses, respectively. Laminates of 10 layers of the films pressed at 250° C and 1500 psi were translucent and had a ceramic content of about 71.5 weight percent.

Example 3

Ethanol/isopropanol (5 ml/300 ml) was placed in a 500 ml Schlenk flask which was attached to a Soxhlet extraction system. The set-up was degassed and pressurized with argon three times. While under a positive pressure of argon, there was placed into the Soxhlet chamber a glass thimble with 10 g (0.25 mole) of 99.5 percent calcium granules.

Refluxing of the ethanol/isopropanol was commenced under a blanket of argon. The reaction was not vigorous. The system was vented slightly for the escape of generated hydrogen. After refluxing for 1 week, there remained in the glass thimble a considerable amount of greyish-white powder, believed to be CaO (hydrolysis product of calcium alkoxide). The adventitious water entered the system via the ethanol that was used. In the reaction pot was dispersed a trace amount of the CaO which was filtered off in an inert atmosphere. The filtration was done through a fine glass frit (4-5.5μ), time about 6 hours. Continuance of drawing a vacuum on the filtrate for about 15 hours produced 27 g of a creme-colored powder.

Analysis (plasma emission) of a 2.5 percent isopropanol solution showed the solid to be Ca-(OCHCH₃)₂ contaminated with about 10 percent Ca(OCH₂CH₂CH₃)₂.

Zirconium n-propoxide propylate (3.81 g), 90 percent calcium isopropoxide (1.64 g), prepared above, and isopropanol (300 ml) were added to a 500-ml Schlenk flask. The mix was refluxed over argon for 30 minutes to give a slightly yellow solution.

To this refluxing solution was added (0.2 ml/min) with stirring a degassed solution of 2.5

ml/2.5 ml H₂O/isopropanol. The addition was added via 1/16 inch (0.16 cm) cannular tube. After the addition (about 1/2 hr) the reaction mixture of finely dispersed white particles continued to be refluxed for 2 hours.

At room temperature the product (a milky dispersion) was allowed to sit in a graduated cylinder. After about 3 days a gravitational sediment volume of 35 ml with 4.4 percent CaZrO₃ was present. On centrifuging the volume was reduced to 14 ml of a 10 percent CaZrO₃ dispersion. A look under the microscope revealed agglomerates as large as 25 μm.

An XRD of the centrifuged sediment calcined to 900° C for 2 hours produced a pattern showing the presence of CaZrO₃ and ZrO₂. Analysis (plasma emission) showed a Ca/Zr atomic ratio of 1.00/1.14.

The ceramic green body was prepared and slip cast to tape by the procedure of Example 2.

Example 4

BaTiO₃/CaZrO₃ (80/20 weight percent) Slip Formulation

After hand mixing the centrifuged sediment volumes of BaTiO₃/isopropanol (4 g/12 ml) and CaZrO₃/isopropanol (1 g/12 ml), there was added 6 ml of 12.5 percent ETHOCEL 45/isopropanol solution. With continued stirring (about 300 rpm) of the dispersion, there was added dioctylphthalate (0.73 g) and 1,2,4-butanetriol (0.73 g). After an additional 30 minutes of stirring, there were added 6 drops of a 0.6 percent solution of the emulsifier in isopropanol. A look at the slip dispersion under a microscope showed a glassy mass of particles of about 2.5 μm with some agglomerates of about 15 μm.

An 8-mil slip was cast and dried at room temperature to give a slightly cloudy film which was unable to be stripped from a glass substrate. It appeared that the film was too brittle. A TGA showed a 66 percent solid ceramic film content. An XRD of the powdered film showed only the BaTiO₃ pattern with an average particle diameter of 116Å (The CaZrO₃ being amorphous did not exhibit an XRD pattern.)

A tablet was pressed out of the powdered film, calcined up to 850° C, and then sintered at 1310° C for 1½ hours. A surface XRD of the sintered tablet showed the presence of [BaCa] [TiZr]O₃. STEM photos of both a fracture and surface of the tablet showed some pores, but looked fairly dense overall, estimated at about 85 to 90 percent dense.

Example 5

According to the procedure of Example 2, the following ratios of reactants were admixed in 500 ml of dry and deoxygenated isopropanol, Ba(i-C₃H₇O)₂ (4.63 g, 0.0182 mole), Y(i-C₃H₇O)₃ (9.67 g, 0.0364 mole), and Cu(C₂H₅O)₂ (8.38 g, 0.0546 mole). The solution was stirred and refluxed for 45 minutes at which time the mixture was hydrolyzed as in Example 2. The hydrolysis resulted in the formation of a solid powder having the nominal composition of YBa₂Cu₃O_{9-y}, such that O_{9-y} = 6.5 to 7.

Claims

1. A process for preparing a ceramic green body comprising:

(a) forming a hydrolyzable solution of at least one compound of the formula A(OR)_x,

wherein A is at least one of the metals Be, Mg, Ca, Sr, Ba, Ge, Pb, Nd, Y, La, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb, Lu, Sb or Bi, and at least one compound of the formula B(OR)_x and

wherein B is Ti, Zr, Sc, Y, La, Nb, Fe, Ta, W, Mn, Sn, Mg, Cu or Zn,

wherein R is a group of the formula C_yH_z wherein y is from 1 to 10,

z is y, 2y, 2y + 1 or 2y - 1, and

x is from 1 to 7,

such that the said compounds are suitable to be hydrolyzed to form a compound of the formula ABO₃, and an alcohol suitable to dissolve the said compounds;

(b) hydrolyzing said hydrolyzable solution to form a hydrolyzed dispersion of said compound of the formula ABO₃ in said alcohol;

(c) concentrating at least a portion of the dispersion to form a sediment;

(d) admixing a binder solution, a plasticizer, and a release agent with said sediment to make a ceramic slip formulation; and

(e) preparing a ceramic green body from the said slip formulation.

2. A process as claimed in Claim 1 wherein the hydrolyzable solution is hydrolyzed by adding water in an amount from 0.5 to 10 percent by weight of the hydrolyzable solution.

3. A process as claimed in Claim 1 or Claim 2 wherein the first and second groups of alkoxides are hydrolyzed together.

4. A process as claimed in any one of the preceding claims wherein the hydrolysis is conducted by adding water to the hydrolyzable solution at a rate from 0.2 to 0.4 cc/min.

5. A process as claimed in any one of the preceding claims wherein A is Mg, Ca, Sr, Ba, Y, La, or Pb.

6. A process as claimed in any one of the preceding claims wherein B is Ti, Zr, Sc, Y, La, Nb, Ta, W, Sn, Mg, Cu or Zn.

7. A process as claimed in any one of the preceding claims wherein said alcohol comprises from 80 to 99 percent by weight of said hydrolyzable solution.

8. A process as claimed in any one of the preceding claims wherein the hydrolyzable solution comprises in total from 1 to 20 percent by weight of compounds of the formula A(OR)_x and B(OR)_x.

9. A process as claimed in any one of the preceding claims wherein a dispersant is incorporated in the said sediment, in an amount of from 0.002 to 0.5 percent by weight based on the hydrolyzed dispersion.

10. A process as claimed in any one of the preceding claims wherein the amount of solvent utilized for the binder solution is from 1 to 6 percent by weight based on the hydrolyzed dispersion.

11. A process as claimed in any one of the preceding claims wherein the amount of binder utilized is from 0.1 to 5 percent by weight based on the hydrolyzed dispersion.

12. A process as claimed in any one of the preceding claims wherein the amount of plasticizer utilized is from 0.01 to 5 percent by weight based on the hydrolyzed dispersion.

13. A process as claimed in any one of the preceding claims wherein the amount of release agent utilized is from 0.01 to 5 percent by weight based on the hydrolyzed dispersion.

14. A process as claimed in any one of the preceding claims wherein the release agent is 1,2,4-butanetriol.

15. A process as claimed in any one of the preceding claims wherein the hydrolyzed dispersion comprises excess water.

16. A process as claimed in Claim 15 wherein the excess water is substantially removed prior to a mixing said binder solution.

17. A process as claimed in Claim 15 wherein the slip formulation comprises a sintering aid.

18. A process as claimed in Claim 15 wherein the ceramic green body is a sheet having a thickness of from 1 to 50 micrometres in thickness.

19. An article prepared utilising a ceramic green body prepared in accordance with a process as claimed in any one of Claims 1 to 18.
